SPECIAL SCIENTIFIC REPORT–FISHERIES No. 263

UNITED STATES DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE

EXPLANATORY NOTE

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for official use of Federal, State or cooperating agencies and in processed form for economy and to avoid delay in publication.

ABSTRACT

This report contains the results of quantitative sampling of eggs of jack mackerel, Trachurus symmetricus, off California and Baja California during 1951 through 1954. Annual distribution charts are included.

JACK MACKEREL EGGS, PACIFIC COAST, 1951-1954

This report contains the results of quantitative sampling of eggs of jack mackerel, Trachurus symmetricus, for the years 1951 through 1954. This report may be considered as an extension of information given by Ahlstrom (1953 and 1954) and Ahlstrom and Kramer (1955 and 1956).

The plankton hauls from which the eggs were taken were made at monthly intervals by agencies participating in the California Cooperative Oceanic Fisheries Investigations which is sponsored by the California Marine Research Committee, and which comprises the following organizations: The Scripps Institution of Oceanography of the University of California, the California Department of Fish and Game, the Hopkins Marine Station of Stanford University, the California Academy of Sciences and the South Pacific Fishery Investigations of the U. S. Fish and Wildlife Service.

The data are presented in six tables:

1a. Monthly totals of jack mackerel eggs for 1951-1954.

1b. Regional distribution of jack mackerel eggs for 1951-1954.

2. Jack mackerel eggs by stage for selected stations in 1951.

3. Jack mackerel eggs for 1951.

4. Jack mackerel eggs for 1952.

5. Jack mackerel eggs for 1953.

6. Jack mackerel eggs for 1954.

These tables give the standard numbers of eggs (see below).

The author wishes to express his gratitude to Dr. E. H. Ahlstrom for the aid given in identifying the material, and assistance in the preparation of this manuscript. Mr. James R. Thrailkill has prepared the figures. The Staff, South Pacific Fishery Investigations have contributed materially to the routine tasks associated with the collection and preliminary processing of the data. My wife, Paula Farris, has helped with the laborious proofreading of this report.

AREA COVERED

The area covered by each of the cruises is given by Ahlstrom (1953 and 1954) and Ahlstrom and Kramer (1955 and 1956). An idea of the location of the several stations occupied during the period 1951 through 1954 may be gained from figure 1. However, the exact location of each station at each occupancy is given by the Staff, South Pacific Fishery Investigations (1952, 1953, 1954 and 1955).

METHODS OF SAMPLING

The methods of sampling are given by Ahlstrom (1952:3-6) and Ahlstrom (1953:4-7).

The plankton net is obliquely hauled from a depth of approximately 140 meters (200 meters of wire out) to the surface. The angle of stray of the towing wire from the vertical is kept as close as possible to 45°. The angle of stray is measured continuously during a haul by means of an inclinometer riding free on the wire. The plankton samples are preserved in their entirety for later examination. Fish eggs and larvae separated from the hauls are standardized to the number under 10 square meters of sea surface.

The manner of designating cruises was changed in 1953 from a system of consecutive numbers to a code based on the year and the month; a conversion table has been given by Thrailkill (1956). The new system used herein gives the year (the first two numbers) and the month (the last two numbers). Thus, 5102 refers to the February cruise of 1951.

In tables 3 to 6, a dash (-) indicates that the station was not occupied or if occupied the sample subsequently was spoiled or broken; NQ - haul not quantitative; U - sample unavailable either because it had been mislaid or used in special studies.

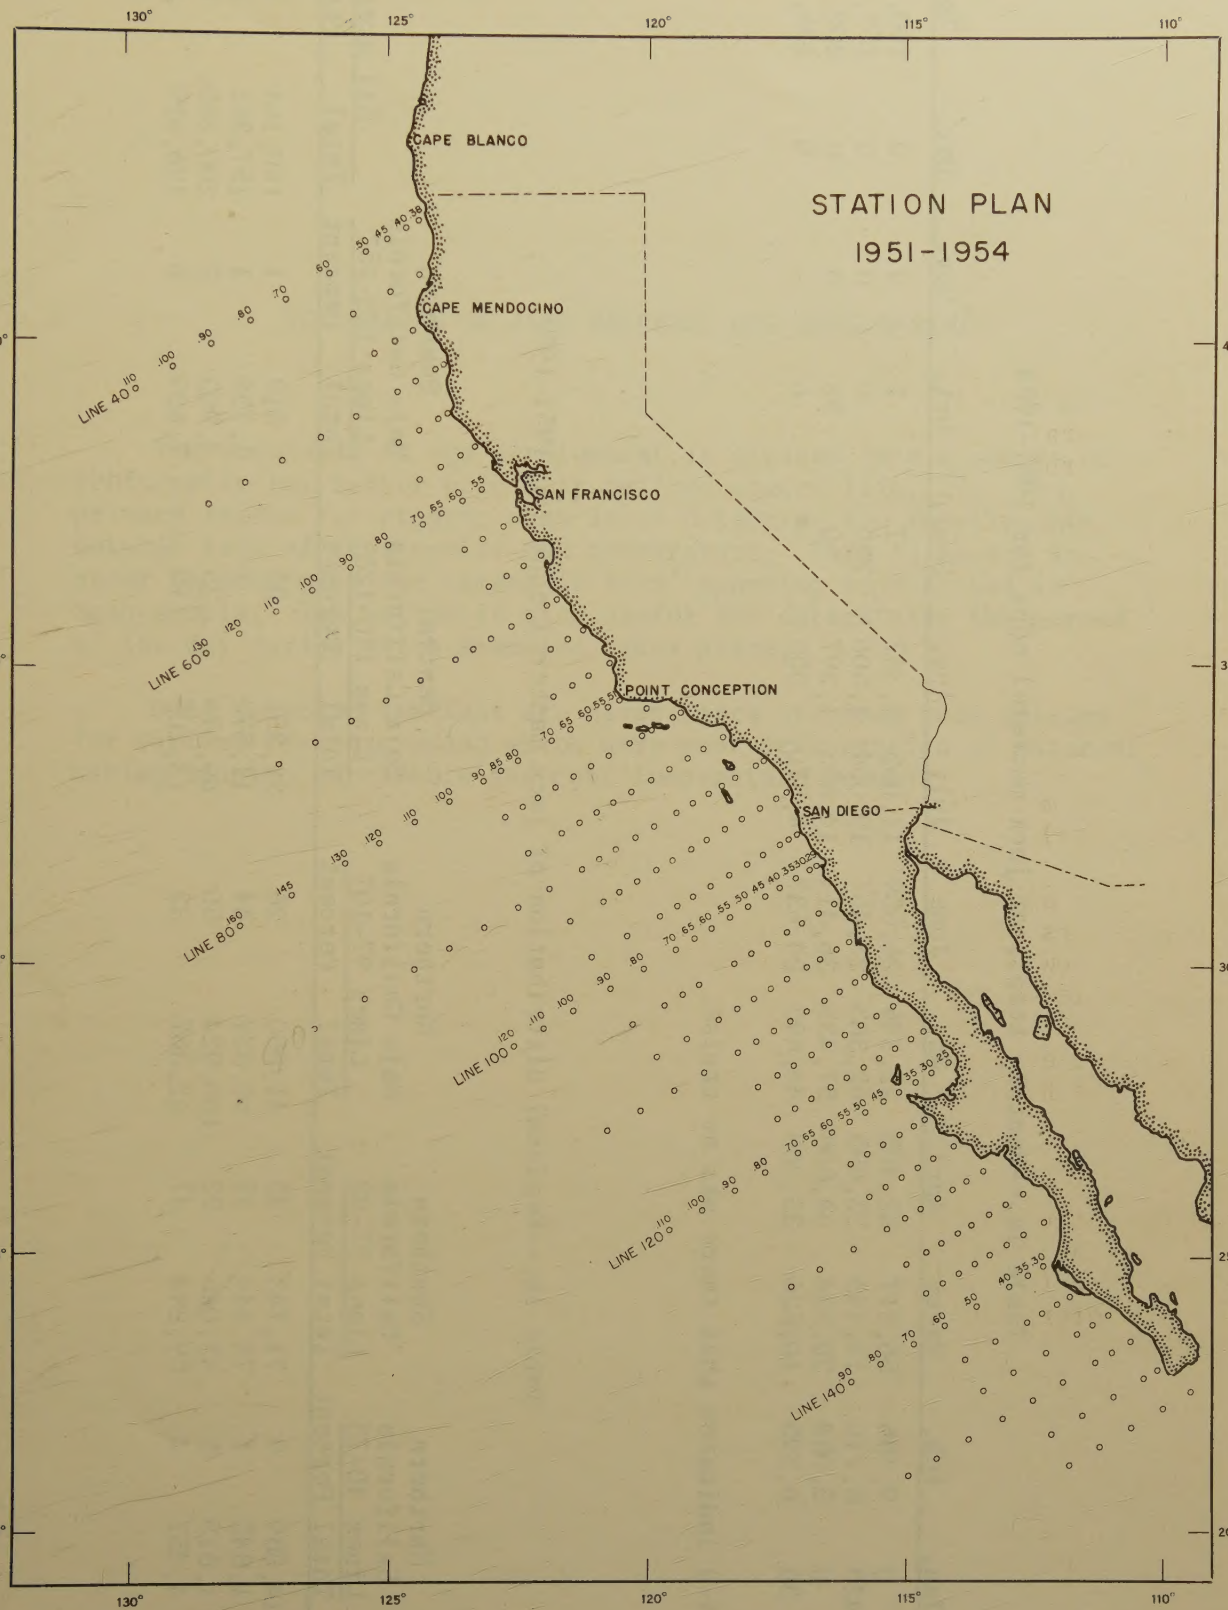

Figure 1.--Station plan, 1951-1954, of the California Cooperative Oceanic Fisheries Investigations.

Table 1a.--Monthly totals of jack mackerel eggs for 1951-1954

THE STAGES OF JACK MACKEREL EGG DEVELOPMENT

The continuum of egg development is divided into a series of arbitrarily but rather precisely defined stages (fig. 2). The primary reason for staging eggs is to determine the relationship between rate of development and temperature. This is needed in order to determine the number of days' spawning represented in each sample. The method is also useful for determining the period of the day during which spawning takes place.

Only selected stations are given since stations were deleted for various reasons, among which were poor preservation of material making staging unreliable and poor temperature records.

Figure 2.--The stages of jack mackerel egg development.

Stage I:	Unfertilized eggs or fertilized eggs prior to cell division.
Stage II:	Begins when the first cell becomes visible on the yolk and ends at the completion of the blastodisc formation (about 256 cell stage).
Stage III:	Starts at the completion of blastodisc formation and is terminated when the germ ring has migrated to its greatest diameter (halfway up the egg).
Stage IV:	Begins as the germ ring moves upward over the greatest diameter and stops when the germ ring lies over the oil globule, prior to blastopore closure.
Stage V:	Begins at blastopore closure and terminates when the tail starts to separate from the yolk.
Stage VI:	Begins when the tail bud comes free of the yolk and stops when the posterior eighth of the body is free of the yolk.
Stage VII:	Begins when the posterior eighth of the body is free of the yolk and stops when the posterior quarter of the body is free of the yolk.
Stage VIII:	Begins when the posterior quarter of the body is free of the yolk, and ends as the tip of the tail approaches the chin. The tail portion of the embryo begins to rotate out of the embryonic plane and the fin-fold is moderately wide.
Stage IX:	Is characterized by the tip of the tail laterally approaching the head. The oil globule comes to lie in the anterio-vertical portion of the yolk sac. The fin-fold is wide and fully formed. At the termination of the stage, the embryo hatches.
Disintegrate:	All jack mackerel eggs whose internal structure is such that staging is impossible fall into this category.

RECORD OF JACK MACKEREL EGGS, 1951

Jack mackerel eggs were collected from February until October, although only negligible amounts were taken during September and October (table 1a). The month of peak occurrence was March, when nearly one-third of the total number of eggs were obtained.

A partial regional analysis (table 1b) indicates that over half the eggs were spawned off California and that very few eggs were spawned to the south of Point San Eugenio (below station line 120).

Of the four years reported, 1951 may be characterized as having a northern distribution accompanied by early spawning.

The quantitative distribution (annual standard haul totals) of jack mackerel eggs is given in figure 3.

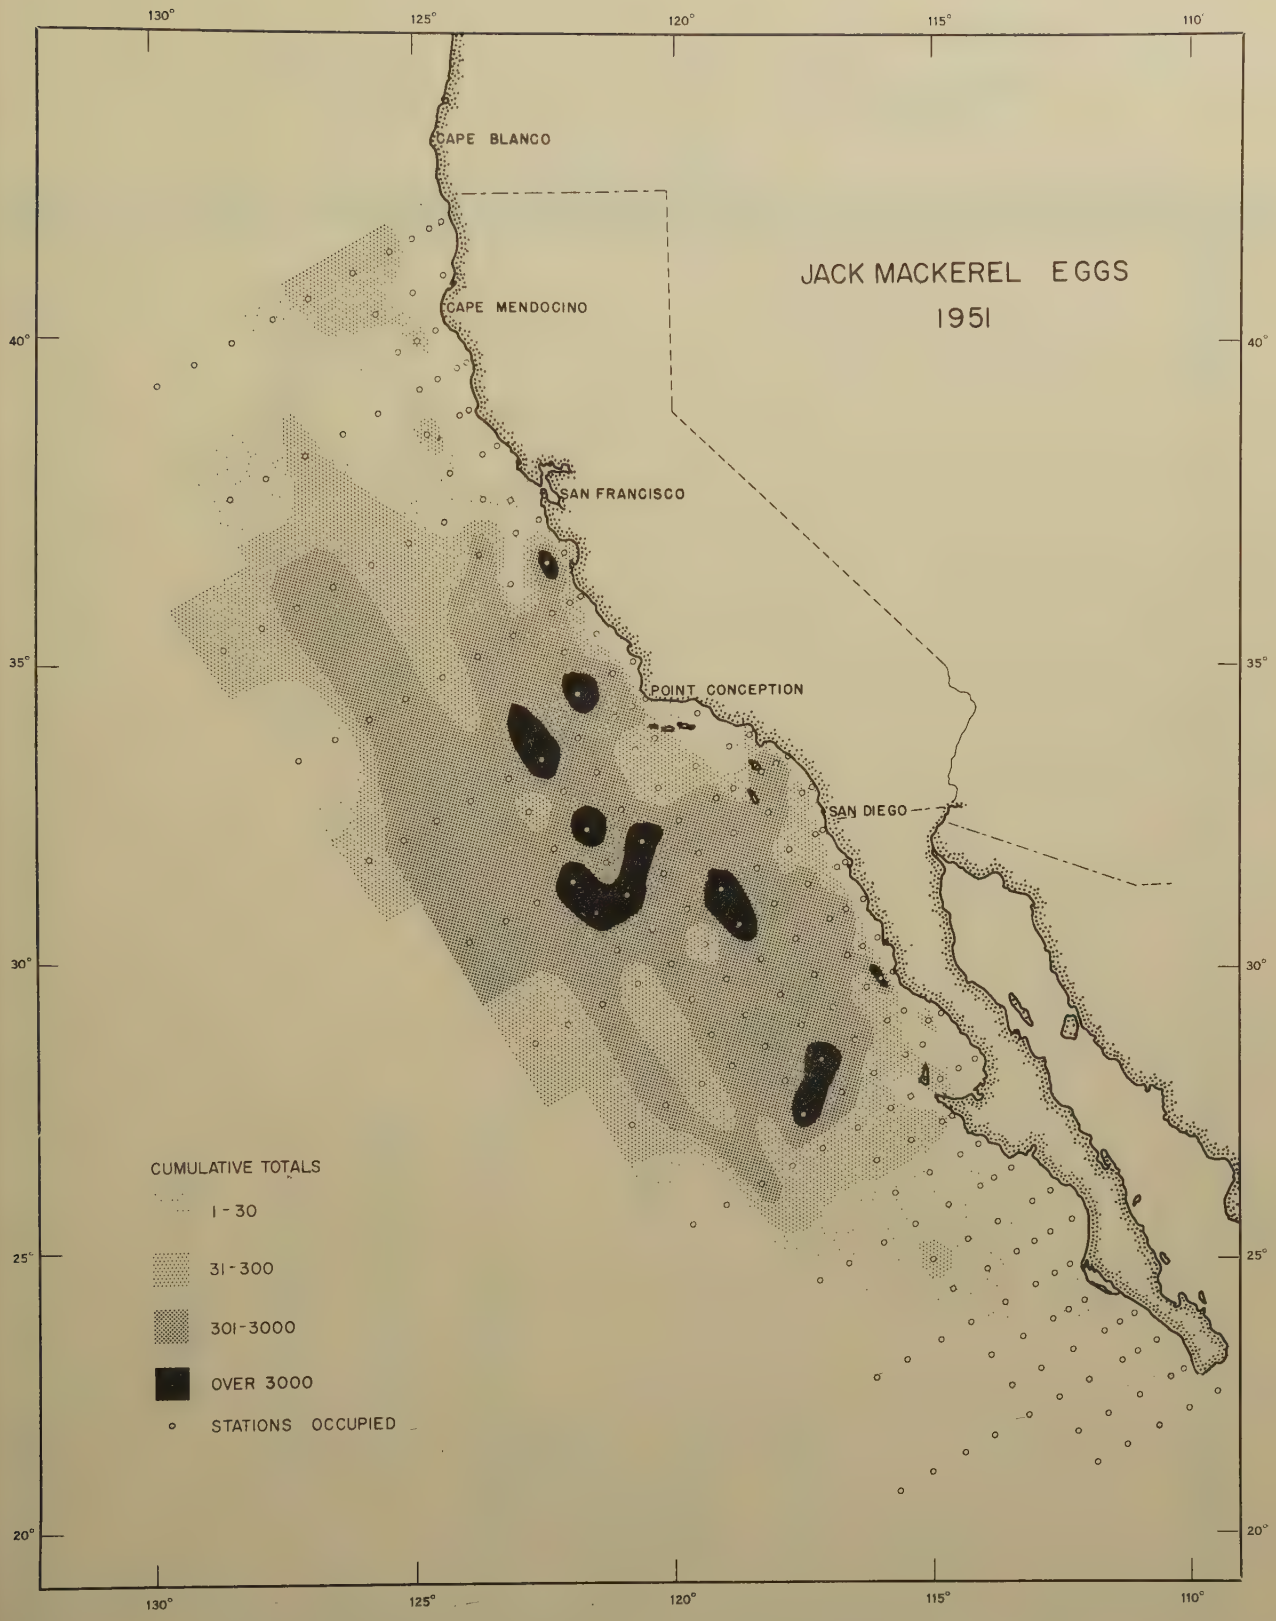

Figure 3.--Jack mackerel eggs, 1951: distribution and relative abundance.

RECORD OF JACK MACKEREL EGGS, 1952

Spawning began in January, rose to a peak in May and ceased by the end of September.

A partial regional analysis indicates that the center of spawning was more compact than in 1951 with over 90 percent of the spawning occurring off southern California and northern Baja California (station lines 77-107). The record shows less spawning off central and northern California (lines 40-73) and off central and southern Baja California (lines 110-157).

The quantitative distribution (annual standard haul totals) of jack mackerel eggs is given in figure 4.

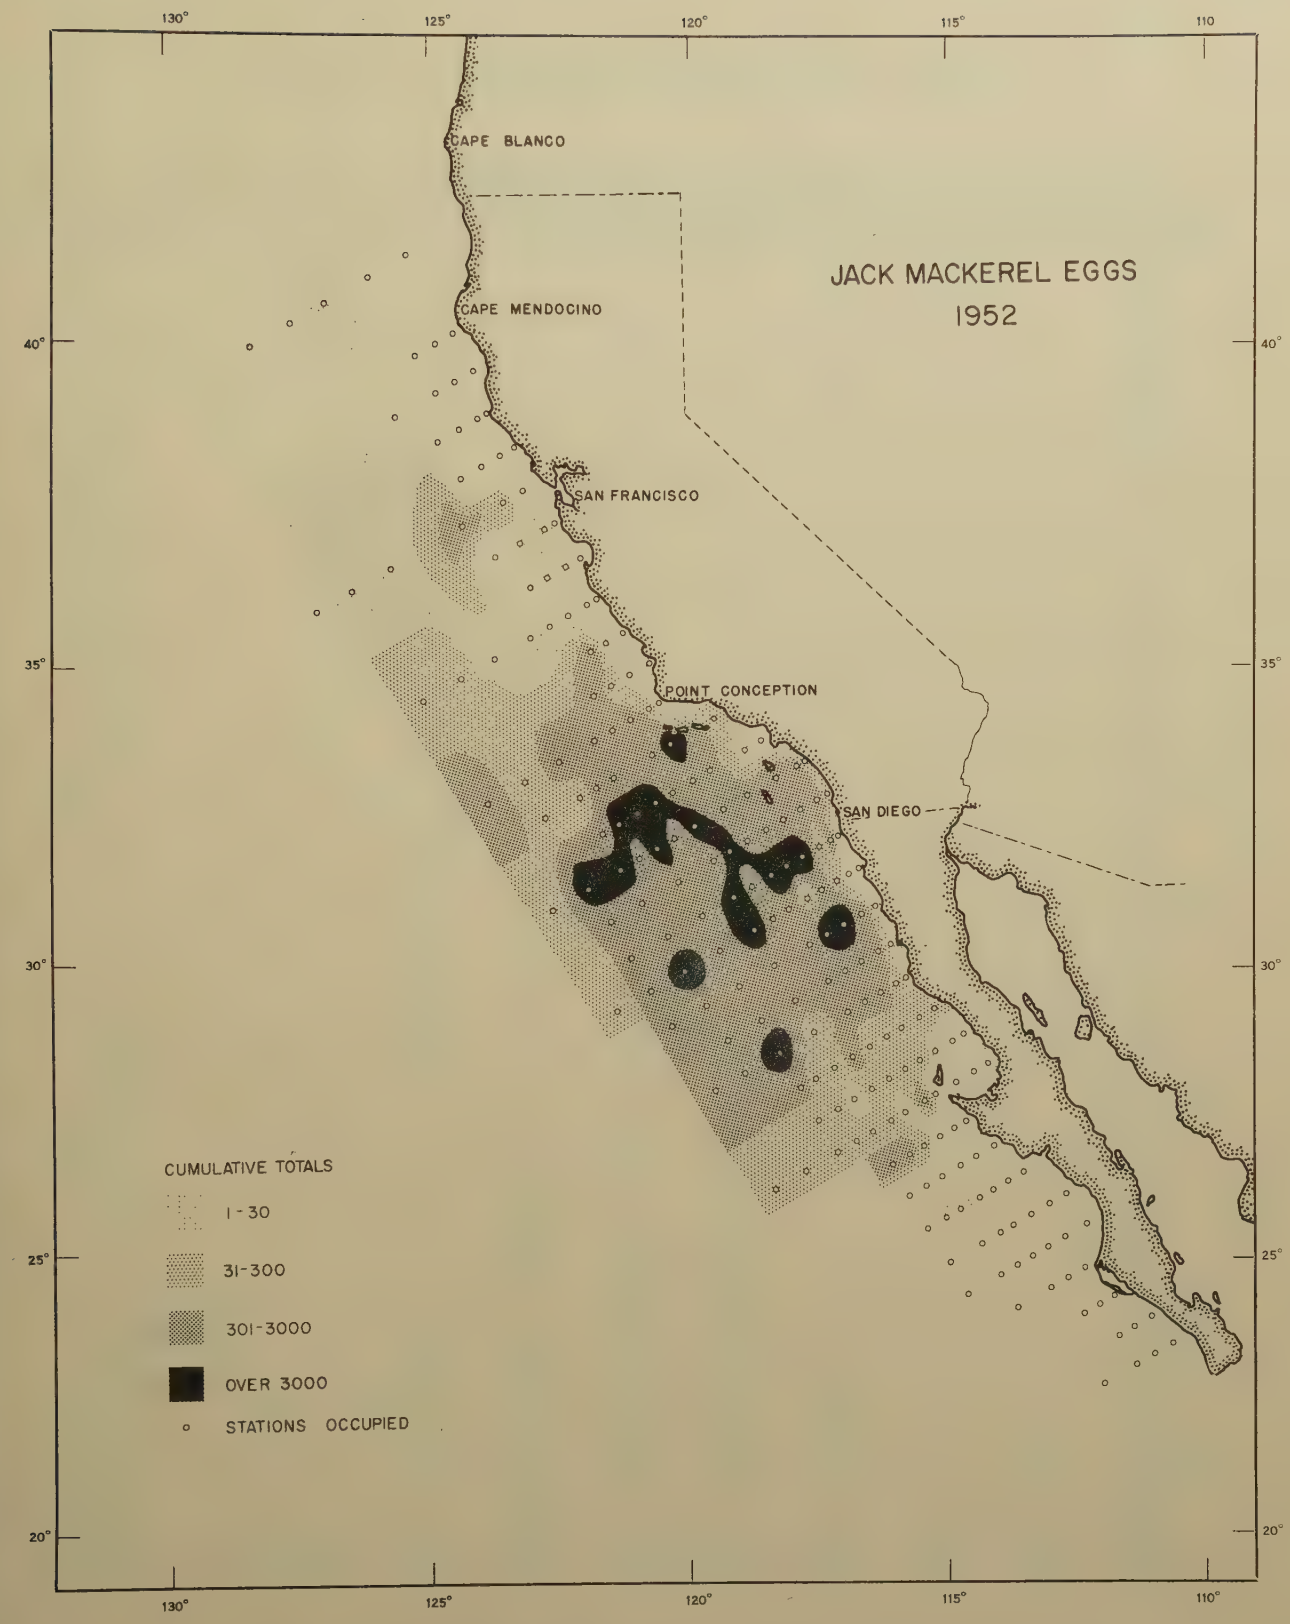

Figure 4.--Jack mackerel eggs, 1952: distribution and relative abundance.

RECORD OF JACK MACKEREL EGGS, 1953

Spawning began in February. The peak came in April this year. No eggs were collected in September but a small number were taken during October.

Half of the eggs were taken from off northern Baja California (station lines 97-107) with the two adjacent regions contributing 46 percent. Of the four years studied, this one has the lowest number of eggs off California, indicating a more southern distribution than usual.

The quantitative distribution (annual standard haul totals) is given in figure 5.

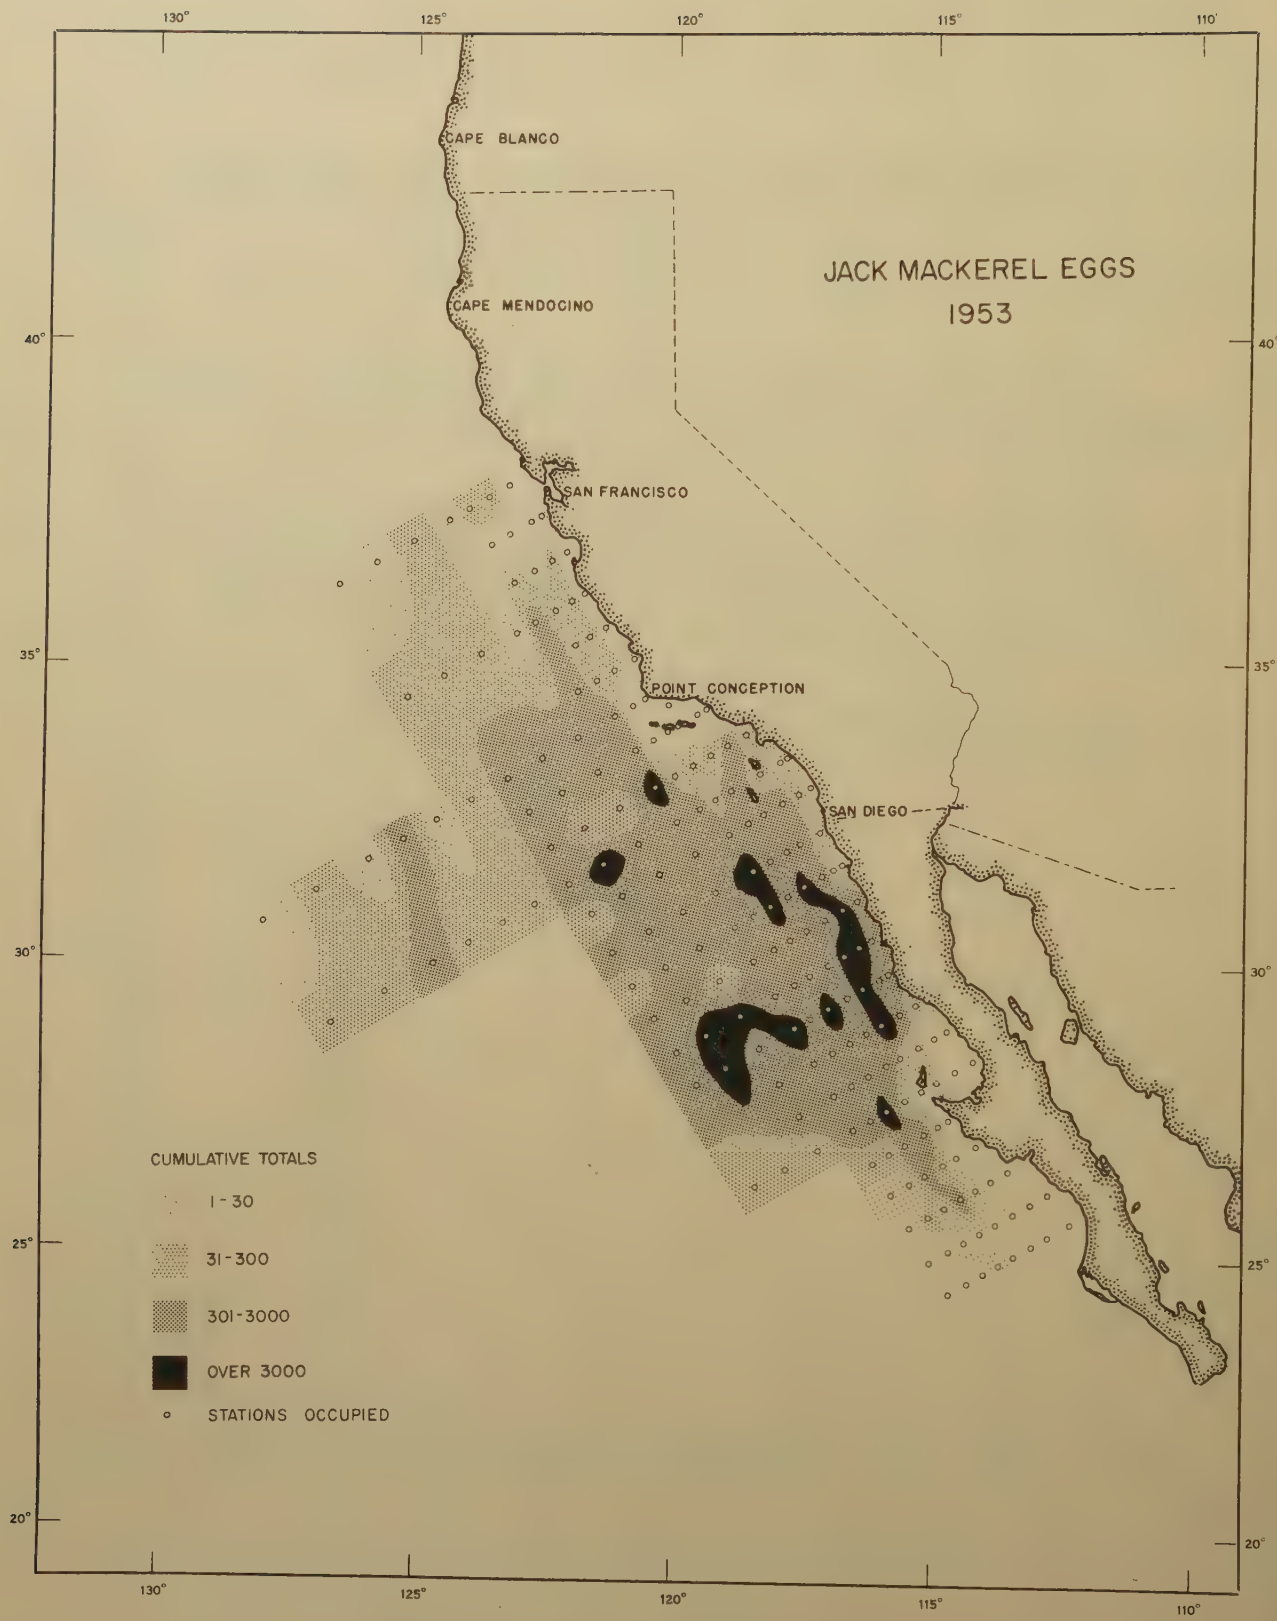

Figure 5.--Jack mackerel eggs 1953: distribution and relative abundance.

RECORD OF JACK MACKEREL EGGS, 1954

A few eggs were taken in January of this year. Over a third of the eggs were taken in May, the peak month. There is some uncertainty as to when spawning ceased since there were no cruises during September and November. However, only a negligible number of eggs were taken during October and records from previous years are consistent with the supposition that no spawning occurred after October.

Like 1951, over half of the spawning occurred off California with the largest proportion occurring off southern California. A relatively large number of eggs taken off southern Baja California (station lines 123-157) is indicative of the wide dispersal of eggs during this year.

The quantitative distribution (annual standard haul totals) of jack mackerel eggs is given in figure 6.

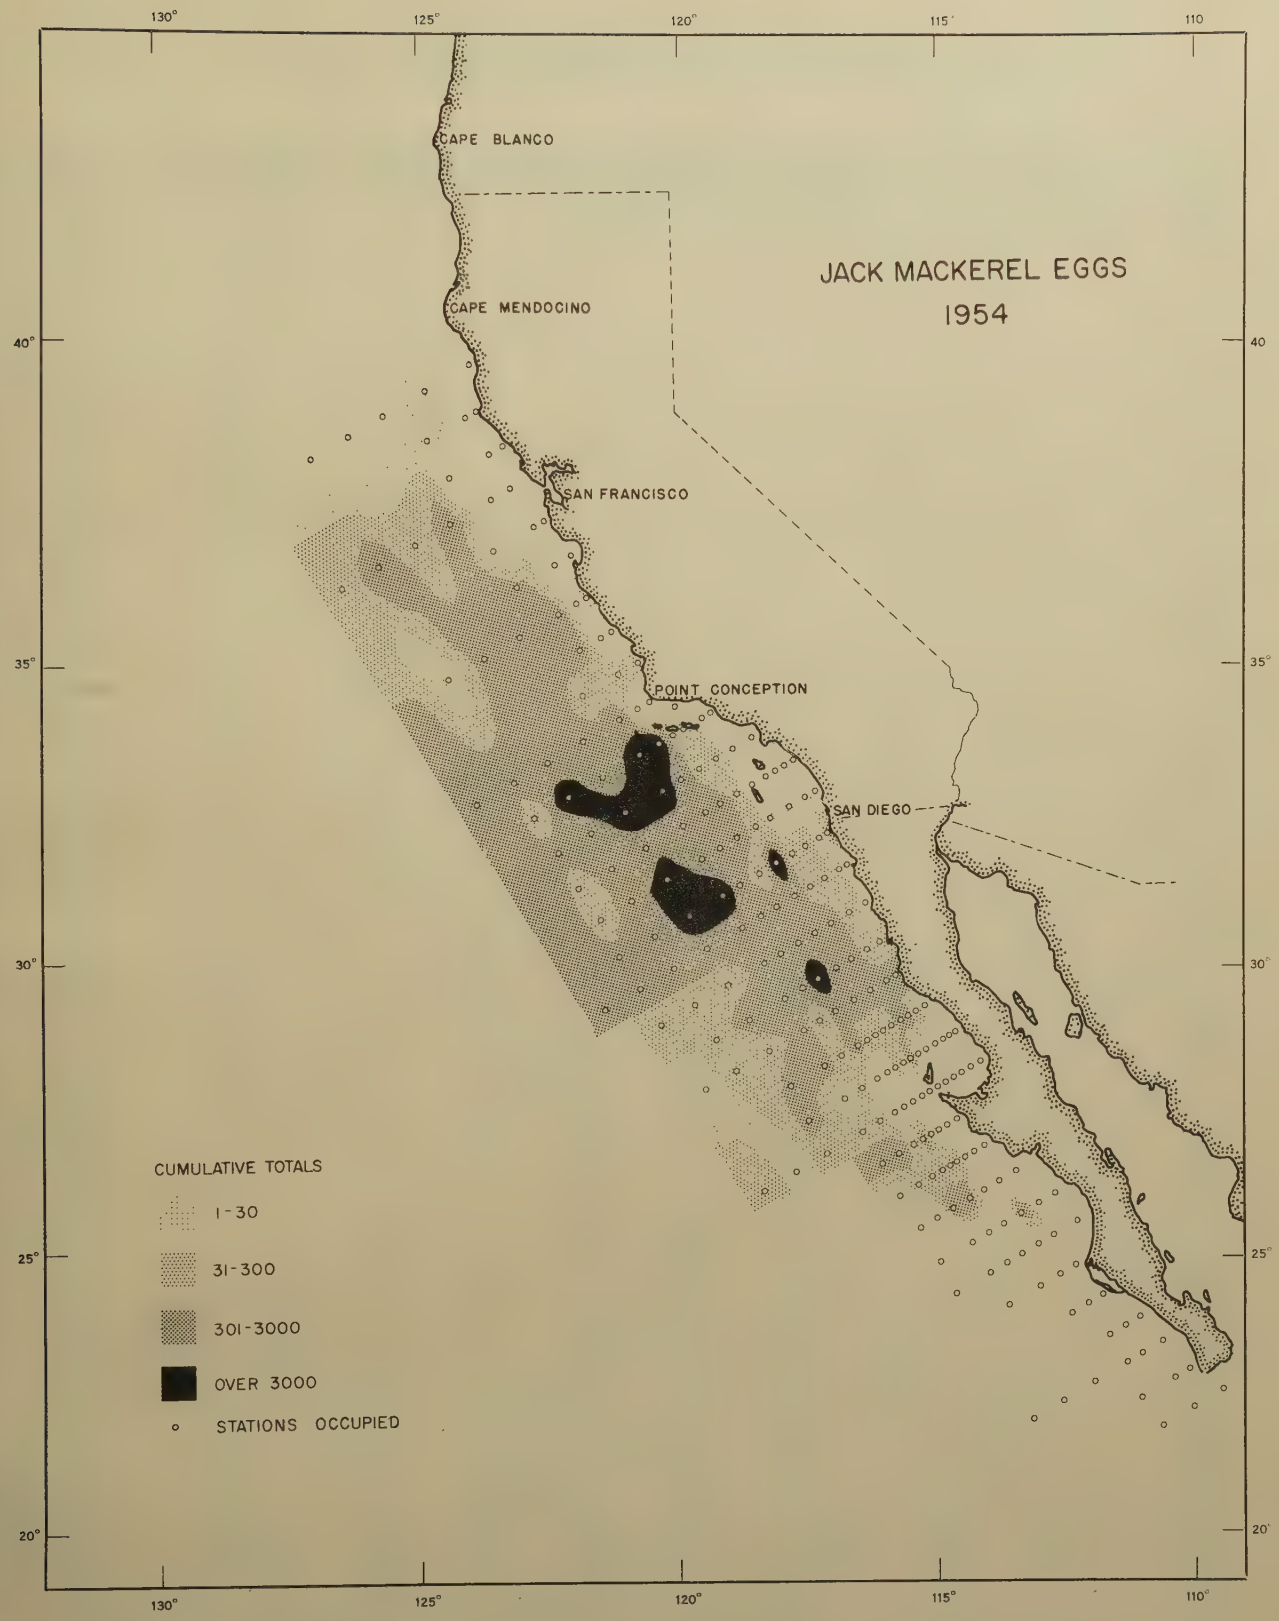

Figure 6.--Jack mackerel eggs, 1954: distribution and relative abundance.
